Abstract : Severe ketoacidosis induces heart failure and cardiac arrest, but its mechanism is unknown. Recently, hydroxy-carboxylic acid receptor 2 (HCA2) was found to be a receptor for a ketone body, β-hydroxybutyric acid (BHB), and is coupled with Gi-GTP binding protein. HCA2 expression was reported in the guinea pig heart. Therefore, using guinea pig cardiac myocytes, we investigated effects of BHB on L-type Ca^{2+} current pre-augmented with β-adrenoceptor agonist, isoproterenol under the whole-cell voltage clamp. BHB significantly reduced the Ca^{2+} current pre-augmented with isoproterenol. The effect of BHB was concentration dependent with IC_{50} of 1.1 mM. Nicotinic acid (NA), another ligand for HCA2, also exerted an effect on the Ca^{2+} current similar to that of BHB. The effects of BHB and NA were reduced by a specific Gi inhibitor, pertussis toxin in the pipette solution. Our results suggest that BHB activates Gi-coupled signal transduction pathway via HCA2 in guinea pig cardiac myocytes. The HCA2-mediated signal transduction may be associated with ketoacidosis-induced cardiac suppression.

Key words : β-hydroxybutyric acid, ketone body, L-type Ca^{2+} current, cardiac myocyte, HCA2 receptor

INTRODUCTION

Ketoacidosis is a life-threatening complication of both type1 and type2 diabetes^{1-3}). However, the mechanism of ketoacidosis affecting cardiac function has not been fully understood. Ketone bodies include β-hydroxybutyric acid (BHB), acetoacetic acid, and acetone. In diabetic ketoacidosis, the ratio of BHB : acetone is elevated from normal (1 : 1) to values as high as (10 : 1)^9). The serum BHB is 0.1 mM or less in normal humans, but could increase to a level higher than 25 mM during ketoacidosis^5). Recently, hydroxy-carboxylic acid receptor 2 (HCA2) was identified as a receptor for BHB^{6}). This receptor was formally called GPR109A, which was initially reported as a receptor for nicotinic acid in adipocytes^{7,8)}, and was coupled with Gi-GTP-binding-protein^{9). GPR109A expression was found not only in adipocytes but also in guinea pig ventricular myocytes^{10).

To assess the mechanism of ketone body affecting cardiac function, we attempted to reveal that BHB stimulates Gi-coupled signal transduction in the heart. To do so, we investigated the effect of BHB on L-type Ca^{2+} current pre-augmented by β-adrenergic agonist, isoproterenol under the whole-cell voltage clamp in guinea pig ventricular myocytes.

MATERIALS AND METHODS

All experiments were performed with the approval of the Animal Research Committee of Fukushima Medical University.

The method of cell isolation and the whole-cell-voltage clamp were described previously^{11). Briefly
the heart was isolated from guinea pig under pentobarbital-anesthesia. Single ventricular myocytes were isolated by perfusing the heart with collagenase (5 mg/50 ml; Wako Pure Chemical Industries, Ltd., Tokyo, Japan) and protase (1 mg/50 ml; Sigma, St. Louis, MO, USA) on Langendorff apparatus. Tyrode solution contained (in mM) 140 NaCl, 5.4 KCl, 1.8 CaCl₂, 1 MgCl₂, 0.33 NaH₂PO₄, 5.5 glucose, 5 HEPES (pH 7.4 with NaOH). The pipette solution contained (in mM) 30 CsCl, 100 CsOH, 3 MgCl₂, 100 aspartic acid, 5 MgATP, 20 BAPTA, 20 HEPES (pH 7.2 with aspartic acid). Membrane currents were recorded by the whole-cell voltage clamp with a patch-clamp amplifier (CEZ2400, Nihon Kohden, Tokyo, Japan). The temperature of the bath solution was kept at 35±0.5°C with a water jacket connected to a thermostat incubator (HAAKE, E15, Berlin, Germany). Patch pipette resistance was 2-4 MΩ when filled with the pipette solution. Recording signals were filtered at 2.5-kHz bandwidth, stored online and analyzed with pClamp Version 9 (Axon Instruments, Union City, CA, USA).

D-(-)-beta-hydroxybutyrate was purchased from MP Biomedicals, LLC (California, USA). BHB was directly dissolved in Tyrode solution. Pertussis toxin (Wako Pure Chemical Industries, Ltd., Tokyo, Japan) at 5 μg was activated by mixing with 50 μl dithiothreitol (100 μM) and 450 μl pipette solution and incubated at 37°C for 15-20 min. Then, 4.5 ml pipette solution was added, so that the final pertussis toxin (PTX) concentration of in the pipette solution was 1 μg/ml12,13). Each experiment was repeated 4 to 5 times. The data were expressed as the means±S.E.M. Statistical significance between two groups was evaluated using Welch’s t-test.

RESULTS

Effect of BHB on L-type Ca²⁺ current pre-augmented by isoproterenol

First we found that BHB alone did not affect the L-type Ca²⁺ current in single ventricular myocytes of guinea pig (data not shown). Then, we tested BHB on the L-type Ca²⁺ current pre-augmented by isoproterenol. A family of depolarizing square voltage pulses were given from the holding potential of −40 mV to +40 mV for 400 ms duration (Fig. 1A inset). Isoproterenol at 0.1 μM in the extracellular Tyrode solution increased L-type Ca²⁺ current (Fig. 1A and 1B). When 10 mM BHB was added to isoproterenol, the Ca²⁺ current was gradually decreased (Fig. 1C). Finally, 1 μM nifedipine was added to completely inhibit the Ca²⁺ current (Fig. 1D). In some cells, positive background currents increased as shown in Fig. 1C and Fig. 1D. These currents were most likely isoproterenol-induced Cl⁻ currents14). We measured the magnitude of the Ca²⁺ current between the peak and at the inactivated level at the end of 400 ms depolarizing pulse at each voltage in order to avoid contamination of the isoproterenol-induced Cl⁻ current. The I-V curves of the Ca²⁺ current were plotted (Fig. 1E). Since the peak potential of the Ca²⁺ current varied between −20 mV and 10 mV among different cells, we employed the value at 10 mV for further analysis.

A concentration-response curve of BHB was obtained (Fig. 2). The peak value of Ca²⁺ current in isoproterenol was set at 100%. BHB at 10 mM significantly inhibited the Ca²⁺ current to 48.9±4.4% (n=5, p<0.001) of the control in isoproterenol. The inhibitory effect of BHB was concentration dependent, and the IC₅₀ value of BHB was approximately 1.1 mM Since the IC₅₀ of BHB to HCA₂ receptor was reported to be 0.7 mM15), our value of 1.1 mM is close enough to that of HCA₂. Therefore, our result suggested that BHB reduced Ca²⁺ current pre-augmented by isoproterenol possibly via HCA₂ receptor in guinea pig ventricular myocytes.

Effect of nicotinic acid on Ca²⁺ current pre-augmented by isoproterenol

If the above result was mediated by HCA₂ receptor, nicotinic acid, another ligand reported for HCA₂, should behave similarly to BHB. Therefore, we tested nicotinic acid instead of BHB. When nicotinic acid at 30 μM was added in the external solution, it inhibited the Ca²⁺ current to 73% of isoproterenol-treated control in this cell (Fig. 3). The I-V curves were superimposed in Fig. 3E. In 5 different cells, nicotinic acid inhibited the Ca²⁺ current to 67±6% of the isoproterenol-treated control. Since the effects of nicotinic acid and BHB were similar, this suggests that the effects may be mediated by HCA₂ receptor.

Effect of pertussis toxin

HCA₂ receptor is coupled with Gi-GTP-binding protein7). Pertussis toxin (PTX) is a specific inhibitor of Gi16). If the effects of BHB and nicotinic acid on the Ca²⁺ current were mediated by Gi, those effects should be suppressed by PTX. As shown in Fig. 4A, in the presence of activated PTX in the
pipette solution, 10 mM BHB did not significantly decrease the pre-augmented \( \text{Ca}^{2+} \) current. Similar results were obtained with 30 \( \mu \text{M} \) nicotinic acid (Fig. 4B). Nicotinic acid decreased the isoproterenol-augmented \( \text{Ca}^{2+} \) current only to 90.8±6.3\% (\( n=4 \)) in the presence of PTX (Fig. 4B). These results further suggest that the effects of BHB and nicotinic acid were mediated by Gi-protein.

**DISCUSSION**

In this study, we obtained the following results. (1) BHB inhibited the L-type \( \text{Ca}^{2+} \) current pre-augmented by isoproterenol, and this effect was BHB-concentration dependent. (2) Nicotinic acid also inhibited the pre-augmented \( \text{Ca}^{2+} \) current in a similar manner to BHB. (3) Pertussis toxin significantly inhibited the effects of BHB and nicotinic acid. (4) Estimated IC\(_{50}\) value of 1.1 mM BHB was close to a reported value of 0.7 mM for HCA\(_2\) receptor. From these results, we suggest that BHB and nicotinic acid activate Gi-mediated signal transduction via HCA\(_2\) in guinea pig cardiac ventricular cells.

L-type \( \text{Ca}^{2+} \) channels in cardiac myocytes are regulated dually; stimulation mediated by \( \text{Gs} \)-coupled receptors and inhibition via Gi-coupled receptors. The former is represented by \( \beta1 \)-adrenergic receptor and the latter by muscarinic M2
KETONE BODY ACTIVATES HCA₂ RECEPTOR IN GUINEA PIG CARDIAC MYOCYTES

receptor. Fig. 5 shows a scheme of the L-type Ca²⁺ channel modulation. Activation of a Gi-coupled pathway inhibits adenyl cyclase, reduce cAMP and protein kinase A activity and inhibit Ca²⁺ channels. This effect cannot be seen in the absence of prior stimulation of Ca²⁺ channels and is therefore called “accentuated antagonism”. In the present study, using this accentuated antagonism we successfully demonstrated that BHB induced Gi-mediated signal transduction pathway possibly via HCA₂ receptor in guinea pig ventricular myocytes.

Isoproterenol is a non-selective agonist of β₁ and β₂ adrenergic receptors. β₂-adrenergic receptor couples to Gq and Gi-proteins in addition to Gs. In canine heart failure model, β₂-adrenergic receptor stimulation activated Gi, and inhibited L-type Ca²⁺ channel. However, in guinea pig cardiac myocytes, the percentage of β₂ receptor is only 7% and is significantly less than 27% in human hearts. Therefore, we estimated that the involvement of β₂-receptor mediated activation of Gi must be negligibly small in guinea pig myocytes we used in this study.

HCA₂ was discovered as an orphan receptor GPR109A in adipose tissue. In adipose tissue, nicotinic acid stimulates this receptor and lowers LDL cholesterol. An exogenous ligand of this receptor is acipimox, which is carboxylic acids of N-heterocyclic compounds. BHB was identified as an endogenous ligand for HCA₂, which is coupled with PTX-sensitive Gi. In this study, PTX in the pipette solution diminished the inhibitory effects of BHB and nicotinic acid on the Ca²⁺ current. This result strongly indicates that Gi is involved in the effect of BHB and nicotinic acid in guinea pig ventricular myocytes, and therefore, supports our view that the receptors for BHB and nicotinic acid are HCA₂.

Because catecholamine levels are elevated in the blood in diabetic ketoacidosis, patients often exert tachycardia. In rats, however, diabetic ketoacidosis decreased the heart rate and contractility. In cardiac sinus node, atrium and atrio-ventricular node, Gi activation leads to opening of K⁺ channels and decreases the heart rate.

In the treatment of ketoacidosis, catecholamines such as dopamine are often used to maintain circulation. However, our results indicated that BHB higher than 3 mM may attenuate Ca²⁺ current pre-augmented by endogenous or exogenous catecholamines and thus may reduce myocardial contraction. So far, sodium bicarbonate administration has been proposed in ketoacidosis only under severe acidosis such as pH <7.1. However, since sodium bicar-

NA: \(n=4\) #; \(p<0.05\) vs. Iso 0.1 \(\mu\)M.
bonate decreases ketone bodies including BHB\textsuperscript{31}. More aggressive administration of sodium bicarbonate may be revalidated in severe ketoacidosis with high levels of catecholamine and BHB in the blood.

Limitations of the present study include the following. Whether our results obtained from guinea pig cardiac myocytes are applicable to human heart should be evaluated. It is not so common to see ketoacidosis so advanced to accompany cardiac dysfunction.

In conclusion, BHB stimulates Gi signaling pathway possibly via HCA\textsubscript{2} receptors and decrease the Ca\textsuperscript{2+} current pre-augmented by adrenergic β stimulation in guinea pig cardiac ventricular myocytes. This BHB effect may be responsible for suppression of cardiac function in ketoacidosis. Further investigation of the BHB effect on cardiac function is necessary.
